

Ipon Buffer

A savings plan that starts
with what your money needs to cover.

For Philippine workers with irregular income

Working synthetic prototype. Mock wallet.
Experimental local AI, with mandatory review.

A payment today has several jobs tomorrow.

PHP 2,000

available after an income payment

PHP 250 per day for essentials

PHP 600 bill due September 30

Next income expected October 2

How much can be set aside while leaving room for the confirmed essentials?

Illustrative September 28, 2026 scenario. Future income and omitted expenses remain uncertain.

The user reviews every plan and every deposit.

1. Describe or enter

Upcoming bills and expected income.

2. Review and confirm

Check amounts, dates and double counting.

3. Choose a deposit

The engine protects planned essentials first.

4. Access and rebuild

Withdraw, then consider an optional refill.

Manual and local AI entry demonstrated. AI drafts fields and has no money-moving tools.

One omitted bill changes PHP 120 to PHP 0.

Confirmed plan	Before	After school bill
Everyday needs, 4 days	PHP 1,000	PHP 1,000
Bills due	PHP 600	PHP 900
Reserve, with 10% margin	PHP 1,760	PHP 2,090
Suggested deposit	PHP 120	PHP 0

The user adds PHP 300 due tomorrow.
The engine recalculates before money can move.

Actual local AI draft, reviewed and confirmed in the browser. Synthetic inputs and funds.

Emergency access separates withdrawal and payment.

PHP 600 withdrawn
PHP 20 left in buffer

Optional PHP 75/week
for an estimated 8 weeks

Actual mock-wallet screen. Withdrawal works after analysis revocation. No refill debit is scheduled.

The tests pass. Impact still needs evidence.

Base synthetic comparison	No saving	Fixed 10%	Ipon
Fully funded shocks / 281	88	95	95
Essential shortfall days	1,437	1,206	1,248
Median buffer days	0.00	1.33	1.27

Ipon has more shortfall days than fixed 10% saving here.
Savings can suppress discretionary spending in this model.

148 backend + 4 frontend tests passed. 90 invented households over 180 days. No measured impact.

AI helps draft. Deterministic rules decide.

Text entry and proposed fields

qwen3:1.7b via local Ollama
Evidence checks clear uncertain fields
User review and confirmation

Confirmed plan and transfers

Exact centavo arithmetic
Fresh recommendation and consent
Atomic transfer with retry protection

Raw model: 8/40 strict cases passed before added checks.
With checks: 11/12 new examples matched; 1 asked for a date.
Different samples and review rules; reliability remains unproven.

Codex review, not independent validation. Raw outputs and replay retained. No live financial integration.

A partner-paid service is the business hypothesis.

Placeholder monthly economics	PHP
Partner fee per active user	20
Variable cost, including AI compute	8
Contribution per active user	12
Fixed operating cost	120,000

10,000

active users at operating
break-even under these
assumptions

No user fee in the concept. No contracted partner. PHP 300,000 one-time integration excluded above.

A 90-day pilot would test comprehension and access.

Days 1-30

8-10 exploratory interviews
Integration and risk review

Days 31-60

Shadow recommendations
No money movement

Days 61-90

Limited opt-in pilot if approved
Measure access and shortfalls

Manual versus AI plan entry: compare confirmed-field errors, time, corrections and understanding of the review step.

Proposed research. Agree sample size, thresholds, comparison and stop rules before launch.

Seeking a Philippine discovery and pilot partner.

A wallet or financial-services partner
and access to prospective irregular-income users.

Next: validate the planning experience, improve AI reliability,
and define a controlled integration pilot.
